How does google calculates its KDJ indicator for its charts?

I've searched all over and cant find a definite way of doing it.
Everybody has different methods.

On same sites, they say:

$$\%K = 100[(C - L5_{close})/(H5 - L5)]$$

C = the most recent closing price

L5 = the low of the five previous trading sessions

H5 = the highest price traded during the same 5 day period.

The formula for the more important %D line looks like this:

$$\%D = 100 \times (H3/L3)$$

Now calculate %J = $3 \times D - 2 \times K$

But when I try that, it doesnt match with google chart's data.

Some other site apply an SMA or EMA of the %K but even that doesnt fit.

Help would be appreciated!
